System 6: Memory Errors Under MultiFinder 2/93

=====  
Article Created: 14 February 1992

Article Change History  
-----

02/02/93 - REVISED

- To indicate that this is valid for System 6 only.

TOPIC -----

I am often asked by Macintosh users running MultiFinder what causes these types of error messages:

- Application has unexpectedly quit (2)
- Not enough Finder memory ...

DISCUSSION -----

In most cases, these error messages appear when there isn't enough memory allocated to the Finder when running under MultiFinder.

When you are running in Finder only, the Macintosh allocates all available memory to the Finder until an application is run. When you are running under MultiFinder, the Finder is treated as an application and is given a set amount of memory to work with.

To determine if your problem is insufficient memory allocated to the Finder when you are running under MultiFinder, restart your Macintosh in Finder only mode. Then try the same function that resulted in the error message. If you don't get the error message, you need to increase the memory allocated to the Finder when you are running in MultiFinder.

How To Increase Finder Memory Allocation  
-----

- 1) Start up your Macintosh in Finder only mode.

- 2) Open the System Folder of the startup disk, and click the Finder file.
- 3) From the File menu, choose Get Info (or simply press Command-I on the keyboard).
- 4) In the Get Info window, increase the amount of memory shown in the Application Memory Size box. Note that any additional memory that is allocated to the Finder will not be available to applications. A good starting point is to increase the memory allocation by 100K.
