PowerBook 500 series: Audio Playthrough from External CD (3/95)

=====
Article Created: 22 March 1995

TOPIC -----

I have a customer who wants to play audio CD's through his internal speakers. He has a PowerBook 500 series computer and a CD300 external drive. He has the audio cables connected to the sound input port. When he attempts to select the Play Through option as described in the Macintosh guide, he does not have that option available.

How can he play audio CDs through the internal speaker? I know that this is an option on AV units and Power Macintosh computers. Why can't he get this selection on the PowerBook 500 series?

DISCUSSION -----

The Audio playthrough option will appear in Macintosh models which have an internal CD player which has the audio input connected to the logic board of the Macintosh via an internal audio cable. This connector is a four prong connector which essentially supplies the same capability as the positive and negative terminal on standard home stereo speakers right and left channel.

The computer will acknowledge this audio connector being present and provide the option for playthrough in the Sound Control panel. The PowerBook 500 series does not provide a connection for audio on it's logic board (the microphone connector does not count, see below). Because of this, it cannot monitor an audio signal from an external audio connector.

An audio connection made to the microphone port on the PowerBook 500 is unable to be monitored by the speakers of the PowerBook 500, until the signal is digitized and then played back through the speakers.

All Macintosh computers with internal CD support have the internal audio connection which will allow the playback of audio CDs through the internal speaker.
